Quadratic Convergence of Newton's Method

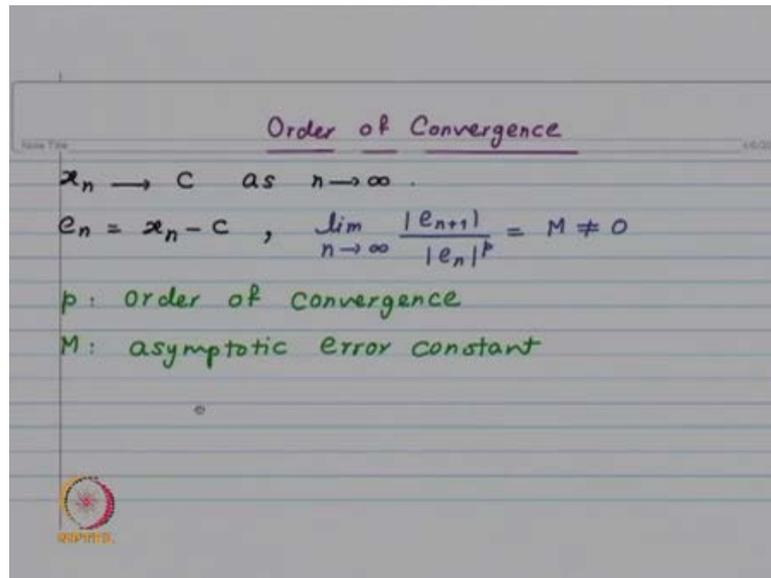

We are considering solution of non-linear equations. Last time we defined newton's method and secant method and also bisection method; so, for the bisection method we have seen that the convergence is very slow. Now, today, we are going to show that newton's method, it converges quadratically or the order of convergence is two; and for secant method it is going to be better than linear convergence, but less than quadratic convergence.

So, let me recall the definition of order of convergence which we defined last time. So, we look at a sequence x_n of real numbers converging to c . Then let e_{n+1} be the difference between c and x_{n+1} , so $c - x_{n+1}$; so, if modulus of e_{n+1} divided by modulus of e_n raise to p , so e_n is going to be error at the n th stage, e_{n+1} is the error at the $n+1$ st stage.

So, look at the quotient, modulus of e_{n+1} divided by modulus of e_n raise to p ; if limit of this is equal to m where m is not 0, so limit as n tends to infinity modulus of e_{n+1} divided by modulus of e_n raise to p ; if it is equal to m not equal to zero, then we say that m is the asymptotic error constant, and p is order of convergence; so, this p we are going to show that, in case of fix point iteration it is going to be equal to 1, in case of newton's method it is going to be equal to 2, and in case of secant method it will be about 1.6; so, better than linear, but less than the newton's method, which is quadratic convergence.

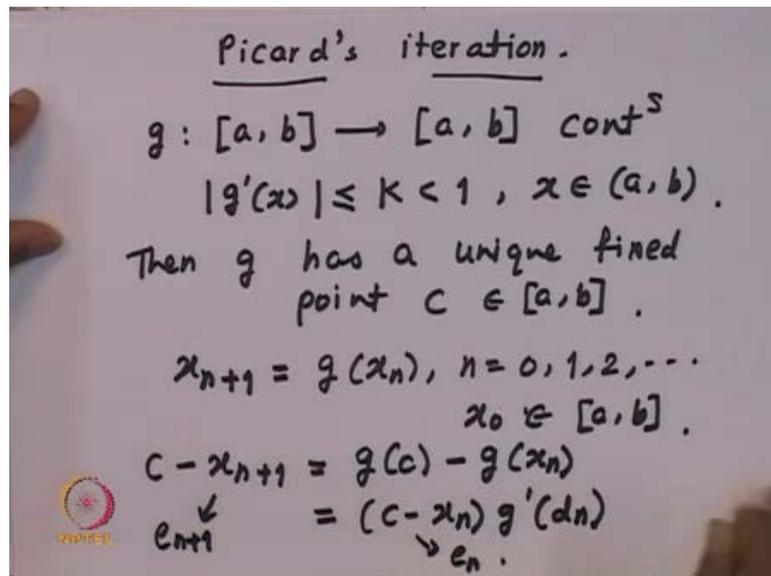

So, first let us show the linear convergence in the fix point method. Now, in all these, like for newton's method, for fix point iteration, in order to show the order of convergence we are going to use mean value theorem or extended mean value theorem; and for the secant method we will use the error in the polynomial approximation.

(Refer Slide Time 03:13)

So, here is the order of convergence, x_n is converging to c as n tends to infinity; by e_n we denote the error x_n minus c , and limit as n tends to infinity modulus of e_{n+1} by modulus of e_n raised to p , if it is equal to $m \neq 0$, then p is the order of convergence, and m is the asymptotic error constant.

(Refer Slide Time: 03:39)

So, let us first look at the fix point iteration or Picard's iteration. So, we have got g to be a map from interval a to b , it is a continuous map, and modulus of g' at x is less than or equal to $K < 1$ for x belong to open interval a to b .

Then g has a unique fixed point c in interval a, b ; and our iteration is x_{n+1} is equal to $g(x_n)$, n is equal to $0, 1, 2$, and so on, and x_0 is starting point which is any point in the interval a, b . So, when I consider $c - x_{n+1}$, this is equal to $g(c) - g(x_n)$ - $c - x_n$ being a fixed point - minus g of x_n ; and now, I use mean value theorem to write the right hand side as $c - x_n$ g' of d_n .

(Refer Slide Time: 05:37)

$$e_{n+1} = e_n g'(d_n).$$

$$\frac{|e_{n+1}|}{|e_n|} = |g'(d_n)| \rightarrow |g'(c)| \neq 0.$$

d_n : between c and x_n .

$$x_n \rightarrow c \Rightarrow d_n \rightarrow c$$

$$\frac{|e_{n+1}|}{|e_n|} = |g'(c)| = M, \quad p=1$$

So, this is our e_{n+1} , and this is our e_n ; look at our e_{n+1} is e_n multiplied by g' of d_n . So, modulus of e_{n+1} divided by modulus of e_n is equal to modulus of g' of d_n , d_n is between c and x_n ; our x_n is going to converge to c , so that will imply that d_n also will converge to c then assuming continuity of the derivative, this will tend to modulus of g' of c .

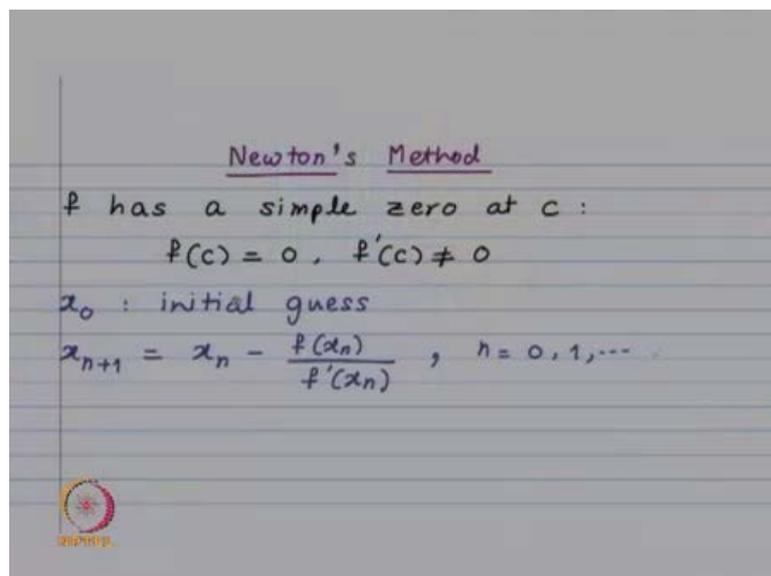

So, if this is not equal to 0 then we have got modulus of e_{n+1} divided by modulus of e_n is equal to modulus of g' of c , so this will be our M , and our p is going to be equal to 1; and **does** for the fixed point iteration the order of convergence is going to be equal to 1. So, this is under the condition that g' of c is not equal to 0; if our fixed point c is such that g of c is equal to c and g' is equal to 0, in that case we are going to get order of convergence to be equal to 2. So, this part we will see little later.

So, now from the fixed point iteration let us go to Newton's method. Now, the Newton's method it need not always converge. So, first we are going to show that if the iterates in the Newton's method, if they converge then they have to converge to a root, if the

convergence is there then it is to the zero of the function; then we will look at an example where the iterates in the newton's method they domain not converge, but they will oscillate.

We will then consider sufficient conditions for the convergence of newton's method. Now, what we are going to do is, this newton's method we will write it as fix point iteration and we have got sufficient condition for convergence of fix point iteration, so we will just translate those, so that gives us a sufficient condition for convergence of newton's method; then we will look at the some other set of conditions which also gives us convergence in the newton's method and then we will look at the order of convergence of newton's method.

(Refer Slide Time: 08:51)

The image shows handwritten notes on a lined background. At the top, the title "Newton's Method" is underlined. Below it, the text states "f has a simple zero at c:" followed by the conditions $f(c) = 0, f'(c) \neq 0$. Then, it says " x_0 : initial guess" and provides the iterative formula $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}, n = 0, 1, \dots$. A small logo is visible in the bottom left corner of the notes.

So, here is newton's method, f has a simple zero at c, so this is our assumption, that means, f of c is equal to 0, f dash c is not equal to 0, x 0 is our initial guess, xn plus 1 is equal to xn minus f xn divided by f dash xn, n is equal to 0 1 2 and so on. And we had seen yesterday interpretation of newton's method as you look at the tangent to the curve at point xn f xn, see where the tangent cuts x axis, so the intersection of the tangent to the curve at xn f xn and the x axis.

That is going to give us our next iterate xn plus 1. So, we need the condition that at no point the tangent should become horizontal, that will be the case if at some point f dash xn is equal to 0; so, that is why **we** our starting assumption is f of c is equal to 0 f dash c

not equal to 0. So, if you are in neighborhood of c $f'(x_n)$ will not be 0 in any case at present we are assuming that the iterates are defined.

(Refer Slide Time: 10:23)

Handwritten mathematical derivation on a whiteboard:

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

$x_n \in [a, b]$, f, f' cont^s on $[a, b]$.

Suppose

$$x_n \rightarrow d, \quad x_{n+1} \rightarrow d.$$

$$f(x_n) \rightarrow f(d), \quad f'(x_n) \rightarrow f'(d).$$

$$d = d - \frac{f(d)}{f'(d)} \Rightarrow f(d) = 0.$$

Now, suppose, iterates converge, so **if we have got**, we have got iterates x_n plus 1 is equal to x_n minus $f(x_n)$ divided by $f'(x_n)$. Suppose, **that** all these iterates x_n **they** lie in the interval a b and function f and its derivate, they are continuous on interval a b .

Now, suppose x_n is converging to d , so suppose then x_n plus 1 also will tend to d , because it is the same sequence by continuity of f $f(x_n)$ will tend to $f(d)$ $f'(x_n)$ or other $f'(x_n)$ will tend to $f'(d)$. So, we get c or rather d is equal to d minus $f(d)$ divided by $f'(d)$; so, that gives us $f(d)$ to be equal to 0. So, **if iterates x_n in the newton's method**, if they are converging then they have to converge to a zero of our function. Now, let us look at an example where the iterates they may not converge .

(Refer Slide Time: 12:02)

$$f: [-3, 3] \rightarrow \mathbb{R}$$
$$f(x) = \begin{cases} \sqrt{x-1}, & x \geq 1 \\ -\sqrt{1-x}, & x < 1 \end{cases} \quad f(1) = 0$$

So, look at this example, f is defined on interval minus 3 to 3 taking real values; and the definition is $f(x)$ is equal to root of x minus 1 x bigger than or equal to 1 and for x less than 1, the definition is minus root of 1 minus x 1 can see that f of 1 is equal to 0, and that is going to be unique 0. In the interval minus 3 to 3 the function has only 1 0 and that is one now we need to calculate the derivative.

(Refer Slide Time: 12:41)

$$f: [-3, 3] \rightarrow \mathbb{R}$$
$$f(x) = \begin{cases} \sqrt{x-1}, & x \geq 1 \\ -\sqrt{1-x}, & x < 1 \end{cases} \quad f(1) = 0$$
$$f'(x) = \begin{cases} \frac{1}{2\sqrt{x-1}}, & x > 1 \\ \frac{1}{2\sqrt{1-x}}, & x < 1 \end{cases}$$
$$x_{n+1} = 2 - x_n$$

$x_{n+1} - 1 = 1 - x_n \therefore$ oscillates between x_0 & $1 - x_0$

So, $f'(x)$ is going to be $\frac{1}{2\sqrt{x-1}}$ if x is bigger than 1; and $\frac{1}{2\sqrt{1-x}}$ if x is less than 1.

So, this function will be differentiable in the interval minus 3 to 3 except at point 1. So, this is our $f'(x)$; now x_{n+1} is going to be equal to $x_n - f(x_n) / f'(x_n)$. So, you have got x_{n+1} is equal to $x_n - f(x_n) / f'(x_n)$, so $f'(x_n)$ is in the denominator, so it will go in the numerator and you will get minus 2 times $x_n - 1$ provided your x_n is bigger than 1.

If x_n is less than 1, then it is going to be minus root of $1 - x_n$ and then there is this 2 into root of $1 - x_n$ again going in the numerator; so, again whether x_n is bigger than 1 or x_n is less than 1, $f(x_n) / f'(x_n)$ is going to be $2x_n - 1$, so this is equal to $2 - x_n$.

From this relation I conclude that $x_{n+1} - 1$ is equal to $1 - x_n$. So, if I start with x_0 , if I take x_0 is equal to 1, and then of course it is we have already found the 0. So, if x_0 is not equal to 1, then our x_1 is going to be equal to $2 - x_0$, it is going to oscillate between x_0 and $2 - x_0$.

(Refer Slide Time: 14:43)

$$x_{n+1} = 2 - x_n .$$

$$x_0 \quad x_1 = 2 - x_0 .$$

$$x_2 = 2 - x_1 = 2 - (2 - x_0) = x_0 .$$

$$x_3 = 2 - x_0$$

$$x_0 \quad 2 - x_0$$

So, we have got x_{n+1} is equal to $2 - x_n$. So, you start with x_0 , x_1 is going to be $2 - x_0$, x_2 will be $2 - x_1$, so it will be $2 - (2 - x_0)$ which is equal to x_0 . So, x_2 is equal to x_0 that will give you x_3 to be $2 - x_0$ x_3 will be equal to $2 - x_0$ and so on.

So, our sequence x_n that is going to oscillate between x_0 and $2 - x_0$; so, in this example we had our function is defined on interval minus 3 to 3, there is a single 0 and that **is 0** is equal to 1. Now, no matter how near you choose your x_0 to one no matter how you are starting point is near to the 0, you are the sequence which you get it is a oscillatory sequence, this is a pathological example.

In general there are more chances of the convergence of iterates provided your starting point is near your 0. Now, in this example if you happened to choose your starting point to be the 0 itself, then you will you have convergence, you are going to get the constant sequence, but otherwise it remains oscillatory and we have no convergence. Now, look at the function, it is continuous on the interval minus 3 to 3, but it lacks differentiability at an interior point.

So, now, let us look at some of the sufficient conditions for convergence of newton's iterate. So, **we have** as I said we are going to try to write newton's method as an fix point iteration and then for the fix point iteration we have got sufficient condition.

(Refer Slide Time: 17:26)

Handwritten mathematical notes on a whiteboard:

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} : \text{Newton's Method.}$$

$$g(x) = x - \frac{f(x)}{f'(x)} : x_{n+1} = g(x_n)$$

$$g : [a, b] \rightarrow [a, b], \text{ cont}^s.$$

$$|g'(x)| \leq K < 1, x \in (a, b)$$

So, our newton's iterates are x_{n+1} is equal to x_n minus $f(x_n)$ divided by $f'(x_n)$. So, if I define my function g to be $g(x)$ is equal to x minus $f(x)$ upon $f'(x)$, then I can write the newton's iterates as x_{n+1} is equal to $g(x_n)$. **So, this i can look at...** so this is newton's method; and the iterates can be written as a fix point iteration for this function g .

Now, for the convergence of Picard's iteration what we had was g should map interval a to b to interval a , it should be continuous; and modulus of $g'(x)$ should be less than or equal to $k < 1$ for x belonging to interval a . So, we needed continuity of our function g , and we needed differentiability over open interval a and the derivative should be less than or equal to k , where k is less than 1 for each x belonging to a . So, under these conditions we showed that g has a unique fix point and no matter what starting point x_0 you choose in the interval a .

The Picard's iterations x_{n+1} is equal to $g(x_n)$, they are going to converge to the fix point our g now is $g(x)$ is equal to $x - \frac{f(x)}{f'(x)}$. So, first thing we need to assume is that, $f'(x)$ should not vanish, so $f'(x)$ should not be equal to 0, so that our function g is defined on the interval a . When we will look at the derivative of g , the second derivative of function f will come into picture, so our function f should be twice differentiable; and then let us calculate $g'(x)$ with $g(x)$ is equal to $x - \frac{f(x)}{f'(x)}$, whatever condition we get we will say that **that** should be less than 1; so, let us write down this condition

(Refer Slide Time: 20:20)

Handwritten mathematical derivation on a slide:

$$g(x) = x - \frac{f(x)}{f'(x)}$$

- 1) $f \in C^2[a, b]$
- 2) $f'(x) \neq 0, x \in [a, b]$.
- 3) $g'(x) = 1 - \frac{f'(x)^2 - f(x)f''(x)}{f'(x)^2}$
 $= \frac{f(x)f''(x)}{f'(x)^2}$
- 4) $g: [a, b] \rightarrow [a, b]$

$$\left| \frac{f(x)f''(x)}{f'(x)^2} \right| < 1, x \in (a, b)$$

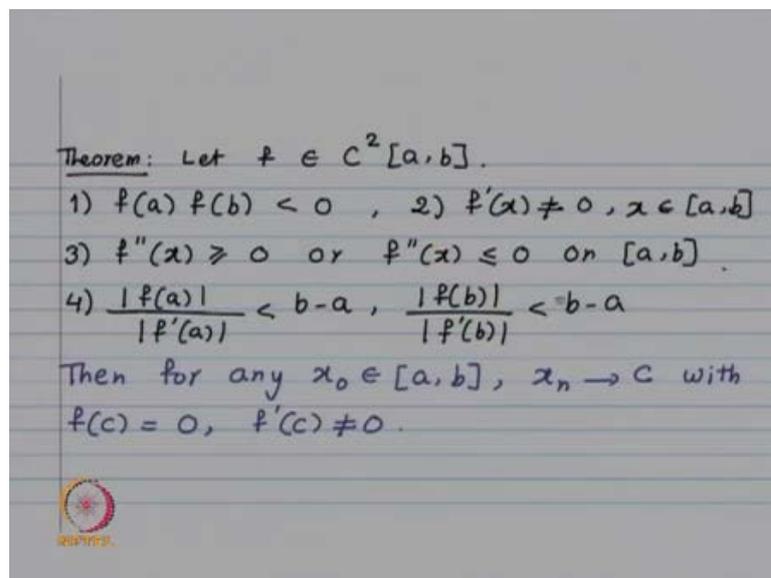

$g(x)$ is $x - \frac{f(x)}{f'(x)}$; so, the first condition is f should be 2 times continuously differentiable on interval a .

Second, $f'(x)$ should not be equal to 0 for x belonging to a ; third condition will be look at $g'(x)$, so $g'(x)$ will be derivative of x is 1 and for $\frac{f(x)}{f'(x)}$ let me

use the quotient rule, so it will be $f'(x)^2$, then denominator into derivative of the numerator, so it will be $f'(x)^2 - f(x)f''(x)$ into derivative of the denominator, so it is going to be $f''(x)$; so, this is going to be equal to $f'(x)^2$ upon $f'(x)^2$; so, we want modulus of $f'(x)^2$ by $f'(x)^2$, this should be less than 2 for x belonging to a, b ; and an important condition is that, g should map interval a, b to interval a, b . So, if these conditions are satisfied, then our newton's method it is going to converge; and we have seen that when it converges it is going to converge to 0.

Also these conditions they imply that g has a unique fix point in the interval a, b and fix point of g is nothing but 0 of f . So, we are going to have a unique 0 of function f and the newton's method or the newton's iterates they are going to converge; now, this is one set of conditions; so, here we had just translated, so let us see more say geometric conditions for convergence of newton's method.

(Refer Slide Time: 23:16)

And these methods are..., so this is as before that f should be 2 times continuously differentiable, then $f(a)$ into $f(b)$ should be less than 0; that means, $f(a)$ and $f(b)$ they are of opposite signs; $f'(x)$ not equal to 0 x belonging to a, b , this also was assumed in the earlier set of conditions; $f''(x)$ bigger than or equal to 0 or $f''(x)$ less than or equal 0 on close interval a, b ; and modulus of $f(a)$ upon modulus of $f'(a)$ should be less than b minus a .

And $f(b) - f(a)$ should be less than $b - a$. Then for any x_0 in (a, b) the Newton's iterates x_n will converge to c with $f(c) = 0$, $f'(c) \neq 0$. So, look at the first condition, $f(a) - f(b) < 0$; so, by the intermediate value theorem f has at least one 0 in the interval (a, b) ; if you assume that $f'(x) \neq 0$ in the interval (a, b) , along with this condition consider $f''(x) > 0$ or $f''(x) < 0$.

The second derivative tells you something about concavity and convexity of the function. Now, if $f''(x)$ is strictly bigger than 0 , that will mean that f' has to be strictly increasing. If $f''(x)$ is strictly less than 0 , that will mean that f' is strictly decreasing; so, this condition $f'(x) \neq 0$, it tells us that f' is going to be of the same sign, it will be either bigger than 0 or it will be less than 0 ; the fact that $f(a) - f(b) < 0$, that tells us that there is at least one 0 , then $f'(x)$ it will be either bigger than 0 or less than 0 ; if $f'(x)$ is bigger than 0 , f will be strictly increasing; if $f'(x)$ is less than 0 , it will be strictly decreasing; that means, there is going to be unique 0 in our interval (a, b) .

Then the third is something about the convexity and concavity; and the last condition that those conditions are imposed to guarantee that if you choose the starting point say $x_0 = a$ or $x_0 = b$, then the next iterate they will lie in the interval (a, b) . Because what we want is all our iterates they should be in the domain of our f , f is defined on interval (a, b) ; so, I am not going to prove this theorem, but I am just going to show you that the last condition implies that if I choose $x_0 = a$, then x_1 is going to be in the interval (a, b) .

(Refer Slide Time: 26:59)

$$x_1 = x_0 - \frac{f(x_0)}{f'(x_0)}.$$

Let $x_0 = a$.

$$x_1 = a - \frac{f(a)}{f'(a)}.$$
$$|x_1 - a| = \frac{|f(a)|}{|f'(a)|} < b - a.$$

\Downarrow

$$x_1 \in [a, b].$$

And the proof is simple. So, our x_1 is going to be equal to x_0 minus $f(x_0)$ upon $f'(x_0)$; let x_0 be equal to a , then we have x_1 is equal to a minus $f(a)$ divided by $f'(a)$. So, modulus of x_1 minus a will be equal to modulus of $f(a)$ divided by modulus of $f'(a)$ and this we are assuming to be less than $b - a$, so this will imply that our x_1 is in the interval $[a, b]$.

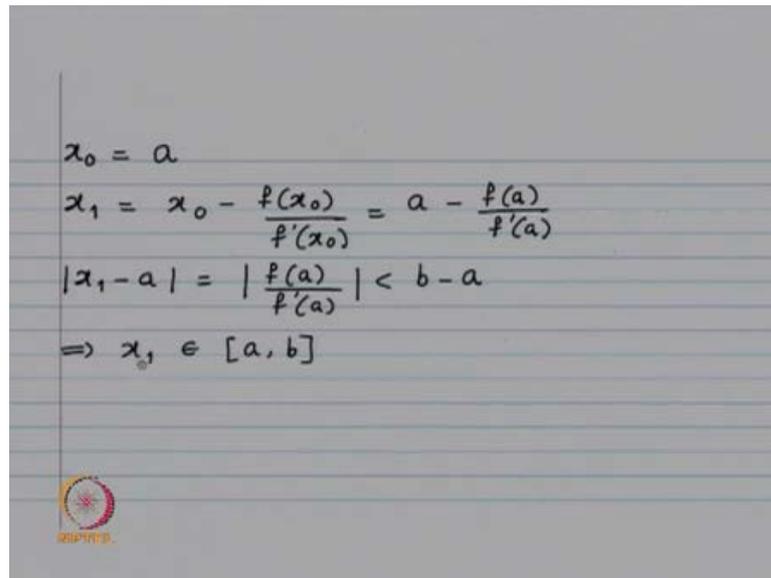

(Refer Slide Time: 27:54)

Theorem: Let $f \in C^2[a, b]$.

- 1) $f(a)f(b) < 0$, 2) $f'(x) \neq 0, x \in [a, b]$
- 3) $f''(x) \geq 0$ or $f''(x) \leq 0$ on $[a, b]$
- 4) $\frac{|f(a)|}{|f'(a)|} < b - a, \frac{|f(b)|}{|f'(b)|} < b - a$

Then for any $x_0 \in [a, b]$, $x_n \rightarrow c$ with $f(c) = 0, f'(c) \neq 0$.

(Refer Slide Time: 28:02)

The image shows a handwritten derivation on lined paper. It starts with the initial guess $x_0 = a$. The next line shows the first iteration: $x_1 = x_0 - \frac{f(x_0)}{f'(x_0)} = a - \frac{f(a)}{f'(a)}$. The third line shows the error bound: $|x_1 - a| = \left| \frac{f(a)}{f'(a)} \right| < b - a$. The final line concludes: $\Rightarrow x_1 \in [a, b]$. In the bottom left corner, there is a small circular logo with a red and yellow design and the text 'SPY' below it.

So, this last condition $\left| \frac{f(a)}{f'(a)} \right| < b - a$, that implied that the first iterate x_1 is going to be in the interval $[a, b]$. And if you choose x_0 is equal to a then the other condition will guarantee that x_1 belongs to interval $[a, b]$. Now, we want to show that the iterates in the Newton's method they converge quadratically.

This is the advantage of Newton's method, like this is one of the plus point that is why Newton's method is so popular; **that** if it converges, it is going to converge quadratically; Picard's iteration it converges only linearly. Now, let me show you that the Newton's method, it is going to converge quadratically; that means, when I consider the error at the n plus first stage, modulus of e_{n+1} divided by modulus of e_n square that will converge to a non-zero constant as n tends to infinity, so because modulus of e_n square, so that too is the order of convergence.

(Refer Slide Time: 29:22)

The image shows a handwritten derivation on a whiteboard. At the top, the Newton-Raphson iteration formula is written: $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$. Below this, it states that $x_n \rightarrow c$ such that $f(c) = 0$ and $f'(c) \neq 0$. The next line shows the Taylor expansion of $f(c)$ around x_n : $0 = f(c) = f(x_n) + f'(x_n)(c - x_n) + \frac{f''(d_n)(c - x_n)^2}{2}$. The error term e_{n+1} is then derived as $|e_{n+1}| = \left| \frac{f''(d_n)}{2f'(x_n)} \right| |e_n|^2$. An NPTEL logo is visible in the bottom left corner of the whiteboard image.

So, our iterates are x_{n+1} is equal to $x_n - \frac{f(x_n)}{f'(x_n)}$, x_n 's are converging to c such that $f(c) = 0$, and $f'(c) \neq 0$. So, let me look at $f(c)$ and write Taylor's series expansion, so it is going to be $f(x_n) + f'(x_n)(c - x_n) + \frac{f''(d_n)(c - x_n)^2}{2}$; so, this is the extended mean value theorem or truncated Taylor series for expansion. Our $f(c) = 0$, so what I do is, I divide throughout by $f'(x_n)$ and I take this first two terms on the other side; so, when I do that I will have $x_n - \frac{f(x_n)}{f'(x_n)} - c$, so what I have done is I am dividing throughout by $f'(x_n)$ and taking the two terms on the other side, so I have $x_n - \frac{f(x_n)}{f'(x_n)} - c = \frac{f''(d_n)(c - x_n)^2}{2f'(x_n)}$; take mod of both the sides, here $x_n - \frac{f(x_n)}{f'(x_n)}$ that is our x_{n+1} .

So, this is modulus of $x_{n+1} - c$, so that is our modulus of e_{n+1} is equal to modulus of $\frac{f''(d_n)}{2f'(x_n)} (c - x_n)^2$ is e_n , so it will be modulus of e_n square. Look at this condition $f'(c) \neq 0$ x_n is tending to c , so for n large enough $f'(x_n)$ is not equal to 0, so we have modulus of e_{n+1} upon mod e_n square is equal to....

(Refer Slide Time: 32:25)

$$|e_{n+1}| = \frac{|f''(d_n)|}{2|f'(x_n)|} |e_n|^2.$$

$x_n \rightarrow c$, d_n between x_n and c .

$$\frac{|e_{n+1}|}{|e_n|^2} = \frac{|f''(d_n)|}{2|f'(x_n)|} \rightarrow \frac{|f''(c)|}{2|f'(c)|} = M.$$

$p = 2$. quadratic convergence

So, you have mod e_{n+1} is equal to mod $f''(d_n)$ by 2 times mod of $f'(x_n)$ into mod e_n square, x_n is tending to c , d_n lies between x_n and c ; so, assuming second derivative to be continuous you get modulus of e_{n+1} divided by mod e_n square is equal to mod $f''(d_n)$ divided by 2 times mod of $f'(x_n)$, which converges to mod $f''(c)$ divided by 2 times $f'(c)$. So, this will be our asymptotic error constant and our p will be equal to 2; so, we have got quadratic convergence; so, this was for the newton's method.

Now, we are going to look at secant method. So, in the secant method what we do is, we start with two points x_0 and x_1 ; in newton's method we have got only one x_0 , and then we looked at the tangent to the curve at x_0 $f(x_0)$; for the secant method as the name suggest we are going to look at two points on the curve x_0 $f(x_0)$ x_1 $f(x_1)$, look at the straight line joining them c where it cuts x axis, that is going to be our x_2 .

And then you consider x_2 and x_1 , look at the secant which passes through x_1 $f(x_1)$, x_2 $f(x_2)$ c , where it cuts x axis that is going to give us x_3 and so on, so this is the secant method. So, as we showed that when the iterates in the newton's method converge, they have to converge to a zero of our function, same thing we will show for the secant method.

Then we are going to show that our formula is going to be symmetric in x_n and x_{n-1} ; x_{n+1} in the secant method, the formula is in terms of x_n and x_{n-1} the values of function.

(Refer Slide Time: 35:39)

Secant Method

$$x_0, x_1 \in [a, b] \text{ given}$$

$$x_{n+1} = x_n - \frac{f(x_n)}{f[x_{n-1}, x_n]} = x_n - \frac{f(x_n)}{\frac{f(x_n) - f(x_{n-1})}{x_n - x_{n-1}}}$$

$$x_n \rightarrow c \Rightarrow f[x_{n-1}, x_n] \rightarrow f[c, c] = f'(c)$$

$$\text{Thus } c = c - \frac{f(c)}{f'(c)} \Rightarrow f(c) = 0$$

So, we will show that it is symmetric and then we will consider the order of convergence in secant method; x_0 and x_1 they are in the interval a, b , what we are doing is $f'(x_n)$ in the Newton's method is replaced by the divided difference based on x_{n-1} and x_n . So, x_{n+1} is equal to x_n minus $f(x_n)$ divided by divided difference based on x_{n-1} and x_n , so I substitute, it is going to be x_n minus $f(x_n)$ divided by $f(x_n) - f(x_{n-1})$ divided by $x_n - x_{n-1}$.

Suppose, x_n converges to c , then x_{n-1} also converge to c , so it is the same sequence, and continuity of the divided difference gives us that this will converge to $f'(c)$, but our definition of divided difference when the arguments are repeated it is $f'(c)$; so, you get $c = c - f(c) / f'(c)$; so, that will give you $f(c)$ is equal to 0. So, whenever the iterates converge, they are going to converge to 0 of our function.

(Refer Slide Time: 37:04)

$$\begin{aligned} \text{Secant Method: } x_{n+1} &= x_n - \frac{f(x_n)}{f[x_n, x_{n-1}]} \\ &= x_n - \frac{f(x_n)(x_n - x_{n-1})}{f(x_n) - f(x_{n-1})} \\ &= \frac{x_n f(x_n) - x_n f(x_{n-1}) - x_n f(x_n) + x_{n-1} f(x_n)}{f(x_n) - f(x_{n-1})} \\ &= \frac{x_{n-1} (f(x_n) - f(x_{n-1})) - f(x_{n-1})(x_n - x_{n-1})}{f(x_n) - f(x_{n-1})} \\ &= x_{n-1} - \frac{f(x_{n-1})}{f[x_n, x_{n-1}]} \end{aligned}$$

Now, here is the symmetric like $x_n + 1$ is equal to $x_n - f(x_n) / f[x_n, x_{n-1}]$; so, if I interchange x_n and x_{n-1} , that means, if I consider $x_{n-1} - f(x_{n-1}) / f[x_n, x_{n-1}]$ I am going to get the same result.

And this result is something expected, because what we are doing is we are looking at point's x_{n-1} and x_n , these we have obtained by the iteration process so far. Now these two points I look at the corresponding points on the curve, I join them by straight line, so then **whether I** the order should not matter, what matters is the two points x_{n-1} and x_n ; whereas, if you look at the formula $x_{n+1} = x_n - f(x_n) / f[x_n, x_{n-1}]$, it is not evident, how I can instead of x_n I can write x_{n-1} and instead of x_{n-1} write x_n .

(Refer Slide Time:38:45)

The image shows a handwritten derivation of the secant method formula on lined paper. The text is written in red and black ink. The derivation starts with the secant method formula: $x_{n+1} = x_n - \frac{f(x_n)}{f[x_n, x_{n-1}]}$. It then shows the steps to simplify the denominator $f[x_n, x_{n-1}] = \frac{f(x_n) - f(x_{n-1})}{x_n - x_{n-1}}$. The final result is $x_{n+1} = x_{n-1} - \frac{f(x_{n-1})}{f[x_n, x_{n-1}]}$.

$$\begin{aligned} \text{Secant Method: } x_{n+1} &= x_n - \frac{f(x_n)}{f[x_n, x_{n-1}]} \\ &= x_n - \frac{f(x_n)(x_n - x_{n-1})}{f(x_n) - f(x_{n-1})} \\ &= \frac{x_n f(x_n) - x_n f(x_{n-1}) - x_n f(x_n) + x_{n-1} f(x_n)}{f(x_n) - f(x_{n-1})} \\ &= \frac{x_{n-1} (f(x_n) - f(x_{n-1})) - f(x_{n-1}) (x_n - x_{n-1})}{f(x_n) - f(x_{n-1})} \\ &= x_{n-1} - \frac{f(x_{n-1})}{f[x_n, x_{n-1}]} \end{aligned}$$

So, one has to do a bit of calculation. So, let us work out the details. So, we have got x_{n+1} is equal to x_n minus $f(x_n)$ divided by the divided difference, I substitute for the divided difference, so I have x_n minus $f(x_n)$ multiplied by x_n minus x_{n-1} and then divided by $f(x_n) - f(x_{n-1})$.

So, now, multiply this x_n by $f(x_n) - f(x_{n-1})$, so I will get $x_n f(x_n) - x_n f(x_{n-1})$, then minus $x_n f(x_n)$ and then plus $x_{n-1} f(x_n)$; so, this $x_n f(x_n)$ will get cancelled, so you have $x_{n-1} f(x_n)$ and minus $f(x_{n-1}) (x_n - x_{n-1})$; so, **we are writing**, what we are doing is, we are adding and subtracting $x_{n-1} f(x_n) - x_{n-1} f(x_n)$ from here, what I have is $x_{n-1} f(x_n)$, so it is this term, then minus $x_n f(x_n) - x_{n-1} f(x_n)$ it is this term; so, I am subtracting $x_n f(x_n) - x_{n-1} f(x_n)$ and I am adding it.

When I do that I will get $x_{n-1} f(x_n) - f(x_{n-1}) (x_n - x_{n-1})$ and this is nothing but the divided difference based on x_n, x_{n-1} . So, this formula and this formula it is the same, its symmetric in x_n and x_{n-1} . So, now, we want to look at the order of convergence in the secant method; earlier what we did was we looked at $f'(c) \neq 0$ for Newton's method, then for $f'(c) = 0$ we wrote the Taylor's formula. Now, here what you will have to do is, you will have to consider the error in the interpolating polynomial and then the remaining proof will be similar.

(Slide Refer Time: 41:02)

Error in the Secant Method

$$f(x) = f(x_n) + f[x_n, x_{n-1}](x - x_n) + \frac{f[x_n, x_{n-1}, x]}{(x - x_n)(x - x_{n-1})}$$

$$0 = f(c) = f(x_n) + (c - x_n) \frac{f(x_n) - f(x_{n-1})}{x_n - x_{n-1}} + f[x_n, x_{n-1}, c](c - x_n)(c - x_{n-1})$$

$$x_n - \frac{f(x_n)(x_n - x_{n-1})}{f(x_n) - f(x_{n-1})} - c = \frac{f[x_n, x_{n-1}, c]}{f[x_n, x_{n-1}]}(c - x_n)(c - x_{n-1})$$

$$|c - x_{n+1}| = \left| \frac{f''(\xi_n)}{2f'(\xi_n)} \right| |c - x_n| |c - x_{n-1}|$$

So, we have got $f(x)$ is equal to $f(x_n)$ plus divided difference based on x_n and x_{n-1} into $x - x_n$ plus this is the error term; so, this is linear approximation; this is a polynomial of degree less than or equal to 1 which interpolates the given function at x_n and x_{n-1} ; this is the error term $\frac{f[x_n, x_{n-1}, x]}{(x - x_n)(x - x_{n-1})}$, so this is from our polynomial interpolation.

So, the results from polynomial interpolation we keep on needing them often like all our numerical integration it was based on the polynomial interpolation; numerical differentiation also the polynomial interpolation it came into picture. Now, for this solution of non-linear equations, linear approximation when you consider the tangent line approximation that means, your interpolation point is repeated twice; you get Newton's method when you take the points x_n and x_{n-1} and fit a polynomial of degree less than or equal to 1 you get secant method.

(Refer Slide Time: 42:41)

Error in the Secant Method

$$f(x) = f(x_n) + f[x_n, x_{n-1}](x - x_n) + f[x_n, x_{n-1}, x] \frac{(x - x_n)(x - x_{n-1})}{2}$$

$$0 = f(c) = f(x_n) + (c - x_n) \frac{f(x_n) - f(x_{n-1})}{x_n - x_{n-1}} + f[x_n, x_{n-1}, c] (c - x_n)(c - x_{n-1})$$

$$x_n - \frac{f(x_n)(x_n - x_{n-1})}{f(x_n) - f(x_{n-1})} - c = \frac{f[x_n, x_{n-1}, c]}{f[x_n, x_{n-1}]} (c - x_n)(c - x_{n-1})$$

$$|c - x_{n+1}| = \left| \frac{f''(\xi_n)}{2 f'(\xi_n)} \right| |c - x_n| |c - x_{n-1}|$$

So, now, you have got this f x, so write 0 is equal to f of c, so I am substituting x is equal to c, so it will be f xn plus c minus xn, this is the divided difference plus f of xn xn minus 1 c and then c minus xn into c minus xn minus 1. As we did in case of newton's method, let us divide by this divided difference, so you are going to have it to be equal to xn, I am going to take this term on the other side and I will be multiplying by xn minus xn minus 1.

(Refer Slide Time: 43:30)

$$0 = f(c) = f(x_n) + \frac{(c - x_n)}{f[x_n, x_{n-1}]} + f[x_n, x_{n-1}, c] (c - x_n)(c - x_{n-1})$$

$$0 = \frac{f(x_n)}{f[x_n, x_{n-1}]} + c - x_n + \frac{f[x_n, x_{n-1}, c]}{f[x_n, x_{n-1}]} (c - x_n)(c - x_{n-1})$$

So, as such what we have is, we have got 0 is equal to f of c plus or is equal to f of x_n plus c minus x_n divided by c minus x_n into multiplied by divided difference x_n x_n minus 1 plus divided difference based on x_n x_n minus 1 c multiplied by c minus x_n c minus x_n minus 1, so I will divide by this divided difference. So, I am going to have 0 is equal to f x_n divided by divided difference based on x_n x_n minus 1 plus c minus x_n plus divided difference based on x_n x_n minus 1 c divided by f of x_n x_n minus 1 and multiplied by c minus x_n c minus x_n minus 1. So, from here I have got this, this divided difference.

Now, if you take this on the other side, then what I am going to get is, so I am going to take this on the another side, so it will be x_n minus f x_n divided by f of x_n x_n minus 1 minus c is equal to the right hand side f of x_n x_n minus 1 c divided by f of x_n x_n minus 1 into c minus x_n c minus x_n minus 1, this is our x_n plus 1.

(Refer Slide Time: 45:58)

$$x_{n+1} = \frac{f[x_n, x_{n-1}, c]}{f[x_n, x_{n-1}]} (c - x_n)(c - x_{n-1})$$

$$|e_{n+1}| = \left| \frac{f[x_n, x_{n-1}, c]}{f[x_n, x_{n-1}]} \right| |e_n| |e_{n-1}|$$

So, we have got x_n plus 1 minus c, take the modulus, so you will have modulus of e_n plus 1 to be equal to modulus of f of x_n x_n minus 1 c divided by f of x_n x_n minus 1 and mod e_n mod e_n minus 1.

(Refer Slide Time: 46:21)

Error in the Secant Method

$$f(x) = f(x_n) + f[x_n, x_{n-1}](x - x_n) + \frac{f[x_n, x_{n-1}, x]}{(x - x_n)(x - x_{n-1})}$$

$$0 = f(c) = f(x_n) + (c - x_n) \frac{f(x_n) - f(x_{n-1})}{x_n - x_{n-1}} + f[x_n, x_{n-1}, c](c - x_n)(c - x_{n-1})$$

$$x_n - \frac{f(x_n)(x_n - x_{n-1})}{f(x_n) - f(x_{n-1})} - c = \frac{f[x_n, x_{n-1}, c]}{f[x_n, x_{n-1}]}(c - x_n)(c - x_{n-1})$$

$$|c - x_{n+1}| = \left| \frac{f''(\alpha_n)}{2f'(\gamma_n)} \right| |c - x_n| |c - x_{n-1}|$$

So, here now we have got, if you compare with the newton's method we had modulus of error plus 1 is equal to something into modulus error square, but now we have got this modulus error and modulus error minus 1.

So, we will see next time that, this is going to make the order of convergence to be less than 2, it will be about one point six. Next time we are going to consider one more method which is known as regula falsi method; and then we will compare these methods, what are the advantages? What are the drawbacks? And then we are going to consider iterative methods for solution of system of linear equation. So, thank you.
